PREVALENCE OF IMPAIRED GLUCOSE TOLERANCE IN PULMONARY TUBERCULOSIS

ABSTRACT

Introduction: Tuberculosis is one of the world’s deadliest infectious diseases which infects one third of the world’s population and kill 1.6 million people each year. On the other hand global burden of diabetes mellitus is going to increase from estimated 180 million currently to 366 million by the year 2030. Both diseases are very common in developing countries like India and Pakistan. Since centuries it was observed that pulmonary tuberculosis is more common in Diabetes Mellitus patients. Recently inverse relation is also observed i.e. high prevalence of impaired glucose tolerance in tuberculosis.

Objective: To evaluate the prevalence of diabetes mellitus in pulmonary tuberculosis.

Study Design: It is cross sectional study.

Site of study: Out patients clinics and wards of chest and general medicine of Chandka Medical College Larkana.

Duration of study: June 2008 to June 2009.

Patients and methods: 136 patients of pulmonary tuberculosis were selected irrespective age sex and duration of symptoms. OGTT was done in all selected patients,

Result: Glucose tolerance test was abnormal in 22 out of 136 patients of pulmonary tuberculosis. Abnormal glucose tolerance is more common in older people (>50 years) and males. It is also seen that abnormality is more common in obese and socioeconomically poor patients who are living in rural areas.

Conclusion: Prevalence of diabetes mellitus is significantly common in patients with pulmonary tuberculosis.

INTRODUCTION

Tuberculosis is one of the world’s common and deadliest infectious diseases. Ninety five percent of tuberculosis cases occur in developing countries, where few resources are available to ensure proper treatment and where Human Immunodeficiency Virus (HIV) infection may be common. Tuberculosis continues to infect an estimated one third of world’s population, cause disease in 8.8 million people per year, and to kill 1.6 million of those affected. The global burden of diabetes mellitus continues to increase from estimated 180 million currently to 366 million by the year 2030 with the greatest increase in developing countries like Pakistan and India[1,2].

In the nineteenth century pathologist observed that active pulmonary tuberculosis was a common finding at postmortem examination of patients with diabetes mellitus[3]. Since then there has been large number of reports upon higher prevalence of pulmonary tuberculosis in diabetic patients[4,5]. Inverse relationship, i.e. high prevalence of diabetes mellitus or impaired glucose tolerance in tuberculoese patients is also being observed since decades[6,7]. In this paper we study the prevalence of impaired glucose tolerance test in patients of pulmonary tuberculosis, because both diseases are very common in our part of the world.

PATIENTS AND METHODS

This is a cross sectional study conducted in outpatient clinics and wards of chest and

RESULT

Out of 136 patients of pulmonary tuberculosis 22(16.17) had abnormal glucose tolerance test (GTT), of which 3(2.2%) had impaired fasting glycaemia, 14 (10.29%) had impaired glucose tolerance and 5(3.67%) were frankly diabetics. Result of oral glucose tolerance is shown in Table 1 in relation to age. Number of impaired glucose tolerance patient is increased which increasing age, 8 out of 30 cases in patients above 50 years of age.

In relation to sex, result of oral glucose tolerance test is shown in Table 2. Relative number of impair glucose tolerance is more in males as compared to females, 14 and 8 respectively (19.71% vs. 13.11%).

Table -3 shows the incidence of abnormal glucose tolerance test in relation to body mass index. It is seen that incidence is increase with increasing body mass index i.e.-e 33% in obese patients, 25% in over weight patients.

Majority of tuberculosis patients belong to rural population, 108 (79.44%) out of 136 patients. It is seen that abnormal glucose
tolerance is more in urban population as compared to rural. The ratio of diabetes is 14.8% (16 out of 108) in rural population. Most patients in study were poor socio economically and there is no difference in abnormal glucose tolerance test related to socio economic conditions.

In 54 patients of pulmonary tuberculosis there is positive sputum smear for acid fast bacilli (AFB). Interestingly it is seen that ratio of developing diabetes mellitus is more in AFB positive patients 12(22.22%) out of 54, while in AFB negative is 10 out of 82(12.19%).

Of all the cases studied, fever was the most common symptom (122 out of 136), while second common symptom is cough which was also the most common symptom in patients with impaired glucose tolerance test. Features of diabetes like increase thirst and polyurea is present in 45% (10 patients) of impaired glucose tolerance as compared to non diabetic tuberculosis (2out of 112 patients) On radiological examination, the most common lesion was infiltration in 8 (36.36%), while cavitory lesion with various fibrosis was seen in 5(22.72%) cases with impaired glucose tolerance test. Lower zone was significantly more commonly involved in those with impaired glucose tolerance test (22.72%).

**DISCUSSION**

Tuberculosis and diabetes mellitus are very common disease of Asia especially India and Pakistan (3). Higher prevalence of tuberculosis in diabetic patients is well known fact(4,5), the suspected reason was decreased immune response in diabetic patients and hyperglycemia as a good growth medium for tuberculosis bacillai. The impaired glucose tolerance in a tuberculosis population is also being increasingly realized. In our study out of 136 patients of pulmonary tuberculosis, the prevalence of abnormal glucose tolerance was 22(16.77%). This result was statistically significant and compares to those found in studies of MK Jain et al(6)(2006) 16.98%, yamagishi et al(7)(2000)14.1%, mugusi et al(8)(1990) 19% and basuglo et al(9)(1999) 19%

The present study revealed that with the increasing age number of impaired glucose tolerance is increased in tuberculosis patients. The higher prevalence of impaired glucose tolerance is elderly patients was also observed in by yamagishi et al (10)(2000) and basuglo et al(11)(1999). This is also routine prevalence of diabetes mellitus that it increases with increasing age.

The prevalence of developing diabetes is more in males and, M K Jain et al(6)(2006) and yamagishi et al(7)(2000) also found the same observation. Majority of patients with impaired glucose test were obese and overweight this may be due to increased prevalence of diabetes mellitus in obese patients. The symptoms of tuberculosis like fever and cough were more frequently present in impaired glucose tolerance test patients and also sputum for AFB smear is more positive in impaired glucose tolerance test patients. This observation may be due to more severe and extensive disease in diabetic patients. In patients with impaired glucose tolerance test and tuberculosis, radiologic findings were also more extensive and involve lower zone more frequently, in contrast to non diabetic tuberculosis patients in which lower zone is rarely involved(12,13).

Several theories have been put forward to explain why tuberculosis patients develop glucose intolerance, zack et al(14)(1973) suggested that glucose intolerance was not merely a reaction to acute tuberculosis infection but rather a prediabetic state. Acute severe stress, fever, inactivity and malnutrition stimulate the stress hormones epinephrine, glucagon, and cortisole which raise the blood sugar level (Guptan et 2000)(15), Roychoudhary and sen(16)(1980) suggested tuberculosis of pancreases as a possible cause. One of the theory suggested by Schwartz & bas(17)(2003) is that amyloidosis, by product of chronic infection is deposited in pancreas. Similarly the higher incidence of chronic calcific pancreatitis occurs in patients of diabetes and pulmonary tuberculosis leading to relative or absolute deficiency of insulin.

**CONCLUSION & RECOMMENDATION**

It is concluded that prevalence of developing diabetes mellitus is significantly high in pulmonary tuberculosis patients, so glucose tolerance test should be done in every patient with pulmonary tuberculosis.
